Building models from categoricity in small cardinals

Marcos Mazari-Armida

25 de octubre de 2018

One of the first things one looses when stepping out of the first-order setting is the compactness theorem, which in particular assures us that if there is an infinite model then there is a model in each cardinality. In this series of talks we will show, in ZFC, that a universal $L_{\omega_1,\omega}$ sentence that is categorical in successive small cardinals has a model in each cardinality and moreover is categorical above a threshold. This result was obtained by Vasey in [Vas]. If time permits we will present stronger results, using weak diamonds, obtained by Vasey and the speaker in [MaVa] and compare them with the results of [Vas].
