

## COMMUTATIVE ALGEBRA HW 5 SOLUTIONS

JC

Due in class Wed 14 September.

- (1) Let  $R$  be a UFD. Show that  $R[x]$  has infinitely many pairwise non-associate irreducibles.

We imitate Euclid's argument to produce an infinite sequence of distinct monic irreducibles (note that a monic irreducible has degree at least one and distinct monic polynomials are not associates).

$x$  is monic irreducible. Let  $f_1, \dots, f_n$  be distinct monic irreducibles. Then  $f_1 \dots f_n + 1$  is monic of positive degree. In its prime factorisation each factor has leading coefficient a unit so we may as well assume that each prime factor is monic. Clearly none of the prime factors appear among the  $f_i$ .

Addendum: The original (broken) version of Q1 asked to show that a UFD with at least one irreducible has infinitely many irreducibles. Whether this is true depends on whether we mean "infinitely many distinct irreducibles" (true as shown by Spas) or "infinitely many non-associate irreducibles" (false as shown by Yimu). The true version is not sufficient to do Q2.

Yimu's example: let  $R$  be the subring of  $\mathbb{Q}$  consisting of rationals  $a/b$  with  $b$  odd. A little thought shows that  $R$  is a local PID (hence UFD) with maximal ideal  $(2)$ ,  $2$  is the only prime up to associates. But of course there are infinitely many units so actually  $2$  has infinitely many associates. Cultural note: this is an example of a DVR (= Discrete Valuation Ring), a class of rings which is important in number theory and geometry.

Spas' proof: If the UFD  $R$  has infinitely many units we are done. So suppose we have only finitely many units. Suppose for a contradiction that there are finitely many primes  $p_1, \dots, p_n$ . Since we are in a UFD the elements  $p_1^t p_2 \dots p_n + 1$  (for  $t > 0$ ) are all distinct so at least one is a nonunit, now we get the usual contradiction a la Euclid.

- (2) Let  $K$  be a field, let  $n \geq 1$  and let  $K(x_1, \dots, x_n)$  be the field of fractions of the polynomial ring  $K[x_1, \dots, x_n]$ . Show that

$K(x_1, \dots, x_n)$  is not ring-finite/ $K$ . Hint:  $K[x_1, \dots, x_{n-1}]$  is a UFD.

Suppose for a contradiction that  $K(x_1, \dots, x_n) = K[r_1, \dots, r_k]$  where  $r_i = f_i/g_i$  for  $f_i, g_i \in K[x_1, \dots, x_n]$  with  $g_i \neq 0$ . Let  $h$  be an irreducible of  $K[x_1, \dots, x_n]$  which does not divide any  $g_i$ . We may express  $1/h$  as a polynomial in the  $r_i$  with coefficients from  $K$ , and clearing fractions we get an equation in  $K[x_1, \dots, x_n]$  of the shape  $g_1^{n_1} \dots g_k^{n_k} = hF$ , contradicting our choice of  $h$ .

- (3) We proved in class that if  $A \leq B \leq C$  are rings with  $A$  Noetherian and  $C$  both module-finite/ $B$  and ring-finite/ $A$  then  $B$  is ring-finite/ $A$ . Show that this is false if we drop the hypothesis that  $A$  is Noetherian.

Let  $R = \mathbb{Z}[x_0, x_1, \dots]$ . This polynomial ring in infinitely many variables is our prototypical non-Noetherian ring.

Let  $I = (x_0^2)_R$  and let  $C = R/I$ . Routinely if  $y_i = x_i + I$  then  $C = \mathbb{Z}[y_0, y_1, \dots]$  (I am cheating a little bit here by identifying  $n \in \mathbb{Z}$  with its coset  $n+I$  in the quotient ring  $C$ , since  $n \mapsto n+I$  is 1-1 it gives an isomorphic copy of  $\mathbb{Z}$  inside  $C$ ).

Let  $A = \mathbb{Z}[y_1, y_2, \dots]$  and let  $B = A[y_0y_1, y_0y_2, \dots]$ . Clearly  $C = A[y_0]$  and since  $y_0^2 = 0$  in fact  $C = (1, y_0)_A$  so that  $C$  is module-finite over  $A$  and hence *a fortiori* over  $B$ .

Suppose for a contradiction that  $B$  is ring-finite over  $A$ , say  $B = A[b_1, \dots, b_l]$ . Since each  $b_l$  is in  $A[y_0y_1, \dots, y_0y_m]$  for  $m$  sufficiently large we will then have that  $B = A[y_0y_1, \dots, y_0y_m]$  for some large  $m$ . In particular  $y_0y_{m+1} \in A[y_0y_1, \dots, y_0y_m]$ .

Going back to  $R$  it follows that there is some polynomial  $F$  with integer coefficients and some  $n \geq m$  such that  $x_0x_{m+1} - F(x_1, \dots, x_n, x_0x_1, \dots, x_0x_m)$  is in  $I$ , that is WLOG we have a polynomial identity for some polynomial with integer coefficients

$$x_0x_{m+1} = F(x_1, \dots, x_n, x_0x_1, \dots, x_0x_m) + G(x_0, \dots, x_n)x_0^2.$$

But this is impossible: two polynomials in  $\mathbb{Z}[x_0, \dots, x_n]$  are equal iff each monomial  $x_0^{a_0} \dots x_n^{a_n}$  has the same coefficient and the monomial  $x_0x_{m+1}$  has coefficient zero on the RHS.

- (4) Let  $X$  be a topological space. We say that  $A \subseteq X$  is *closed* iff its complement  $X \setminus A$  is open. Given a ring  $R$ , identify the prime ideals  $P$  such that  $\{P\}$  is closed in  $\text{Spec}(R)$ .

Using the definitions,  $\{P\}$  is closed iff  $\text{Spec}(R) \setminus \{P\}$  is open iff for every prime  $Q \neq P$  there is  $a$  such that  $Q \in O_a \subseteq \text{Spec}(R) \setminus \{P\}$  iff for every prime  $Q \neq P$  there is  $a \in P \setminus Q$  iff for every prime  $Q \neq P$  we have  $P \not\subseteq Q$ .

If  $P$  is maximal then clearly this holds. If  $P$  is not maximal then  $P \subsetneq Q$  for some maximal (hence prime)  $Q$ . So in conclusion  $\{P\}$  is closed iff  $P$  is maximal.
